

Functional Languages

5th Lecture

Hi!

Lists recap

`[1, 2, 3]` ✓ `[True, False]` ✓

`[1, True]` ✗

- ▶ Homogenous data structure
- ▶ Every list can be built using `[]` and `(:)`
- ▶ Type is written in brackets. e.g. `[Integer]`

`1 : 2 : 3 : []`
 └───┬───┘
 `[3]`
 └──────────┘
 `[2, 3]`

Creating long lists

[1, 2, 3, 4, ..., 100] → [1..100]

Eq	==
Int	Integer
Char	String

- ▶ Range expressions
- ▶ Can be used with any type in Enum type class
- ▶ Check with :info Enum in ghci
- ▶ Many forms:
 - ▶ increasing, decreasing
 - ▶ finite, infinite
- ▶ Example: odd, even numbers, alphabet

inc	dec
finite	infinite

List comprehensions

$[z * n \mid n \in [1..10], n > 5, \text{even } n]$

output expr. generator filters

- ▶ Creating list from one input list
- ▶ Can filter elements of the input list
- ▶ Parts: output expression, generator, filters (optionally)
- ▶ Example: square numbers, divisors, positive integers $[1, 1, 2]$

List comprehensions

- ▶ Creating list from one or more input list
- ▶ Can filter elements of the input lists
- ▶ Cartesian product of input lists
- ▶ Parts: output expression, generators, filters (optionally)
- ▶ Example: hour-minute pairs, dominoes, nested list of divisors

List comprehensions with Strings

- ▶ Remember, `String` is `[Char]` in Haskell
- ▶ Can be input of a list comprehension
- ▶ Example: upper case letters, upper case to lower case, all letters are upper case, count words
